XI CLASS BIOLOGY NOTES CHAPTER – 13: PHOTOSYNTHESIS IN HIGHER PLANTS

Photosynthesis is the process by which plants, some bacteria and some protistans use the energy from sunlight to produce glucose from carbon dioxide and water. It is an enzyme regulated anabolic process.

$$6CO_2 + 12H_2O \xrightarrow{Light} C_6H_{12}O_6 + 6H_2O + 6O_2$$

Importance of photosynthesis:

- Primary source of food
- Release O₂ to atmosphere

Early Discoveries

- **Joseph Priestly**: Candle with bell jar and mouse experiment He concluded that air is necessary for the growth of a plant. He discovered the fact that plants restore oxygen in the air.
- **Jan Ingenhousz**: Experiment with aquatic plant in light and dark He concluded that sunlight is essential for plant processes that purify the air.
- **Julius Von Sachs**: Green parts of plant make glucose and store as starch.
- T.W. Engelmann: Spilt light using prism into 7 colours (VIBGYOR) Green algae *Cladophora* placed in a suspension of aerobic bacteria Bacteriawere usedto detect the sites of O₂ evolutions.
- Cornelius van Niel: He did experiment with purple and green bacteria and demonstratedphotosynthesis is a light dependentprocess with hydrogen from H₂O reduces CO₂ to carbohydrates. He concluded that oxygen comes from H₂O, and not from CO₂. Finally, the correct equation for photosynthesis was discovered.

$$6CO_2 + 12H_2O \xrightarrow{Light} C_6H_{12}O_6 + 6H_2O + 6O_2$$

Site of Photosynthesis

- Green leaves, green stems and floral parts (sepal)
- Chloroplast found in mesophyll cells of leaves
- In chloroplast the membrane system is responsible for trapping the light energy and also for the synthesis of ATP and NADPH. Where stroma has enzymes for the reduction of CO2 in to carbohydrates (sugars)

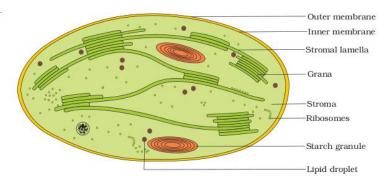

Figure 13.2 Diagrammatic representation of an electron micrograph of a section of chloroplast

Pigments Involved in Photosynthesis

4 types of pigments may be present in leaves: Chlorophyll a Photosynthetic Chlorophyll b **Pigments Xanthophylls** Carotenoids Carotenoids Chlorophyll a Chlorophyll b Xanthophylls (yellow or yellow-orange) (bright or blue (yellow green) (yellow) green) Rate of photosynthesis Absorption Chlorophyll b

- An **absorption spectrum** is the graph plotted against the fraction of light absorbed by the pigment.
- An **action spectrum** is the rate of a physiological activity plotted against the wavelength of light.
- Photosystems are pigments that are organized in the thyllakoid membrane in to two different photosystems (PS 1 & PS 11)
- Each PS has one specific chlorophyll a, and many other accessory pigments bound by proteins.
- Chlorophyll a forms the reaction centre (actual reaction takes place) other pigments form the light harvesting complex (LHC) called antennae.
- PS 1 reaction centre is p700 (chlorophyll –a absorbs light at 700 nm)
- PS 11 reaction centre is p680 (chlorophyll –a absorbs lightat 680 nm)

Light Reaction (Photochemical Phase)

This phase directly depends on light. The pigments absorb light energy and produce ATP.

Includes:

- Light absorption
- Water splitting
- Oxygen release

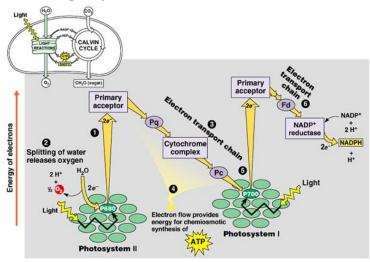

Formation of ATP and NADPH, which is then used in the biosynthetic phase

- Pigment molecules bound to the proteins form LHC (light harvesting complexes). LHC are located within two photosystems – PSI and PSII
- Each photosystem has two parts:
 - Reaction centre consisting of chlorophyll *a* molecule
 - Antennae consisting of accessory pigments, which increase the efficiency of photosynthesis by absorbing different wavelengths of light
- Reaction centre is different in both photosystems:
- PSI P700; since chlorophyll *a* has absorption peak at 700 nm here
- PSII P680; since chlorophyll *a* has absorption peak at 680 nm here.

Photo-Phosphorylation

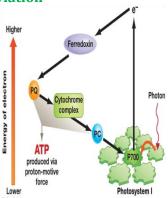

- The process of formation of ATP in chloroplast in the presence of sunlight
- Photo-phosphorylation is of two types:
 - 1. Non-cyclic photo-phosphorylation
 - 2. Cyclic photo-phosphorylation

Non-Cyclic Photo-Phosphorylation

- PSII absorbs 680 nm wavelength of red light, causing electrons to become
 excited and these electrons are then accepted by an electron acceptor, which
 sends them to an electron transport system.
- Electron transport system transfers the electrons to PSI.
- Electrons in PSI are simultaneously excited on receiving a wavelength of 700 nm.
- From the electron acceptor, electrons are transferred to the molecule of NADP+.
- Addition of these electrons reduces the NADP+ to NADPH+ H+.
- Since the electrons lost by PSII do not come back to it, this process of formation of ATP is called non-cyclic photo-phosphorylation.

Cyclic Photo-Phosphorylation

- In this scheme, only PSI is functional. Hence, the electrons are circulated within the photosystem.
- This results in a cyclic flow of electrons.
- This scheme could possibly be occurring in *stroma lamellae* because it lacks both PSII and NADP reductase enzyme.
- This cyclic flow results only in the synthesis of ATP, and not of NADPH + H+.

Splitting Of Water

- Water splitting complex is associated with PSII.
- Manganese, chlorine, etc., play an important role.
- The light-dependent splitting of water is called photolysis

•
$$2H_2O \rightarrow 4H^+ + O_2 + 4e^-$$

- Electrons formed are used for replacing the electrons lost from P680.
- P680 absorbs light and becomes as a strong oxidizing agent and splits a
 molecule of water to release oxygen. Oxygen is liberated as a by-product of
 photosynthesis.
- Protons are used for the formation of reducing power NADP to NADPH+.

Differences between Non-cyclic and CyclicPhotophosphorylations:

	Non- cyclic Photophosphorylation	Cyclic Photophosphorylation
1.	Photolysis of water takes place.	No photolysis of water occurs.
2.	Both PS I and PS II are involved.	Only PS 1 is involved.
3.	Electrons are not cycled.	The electrons released by PS I come back to PS I itself.
4.	Both ATP and NADPH are produced.	Only ATP is formed.
5.	Oxygen is liberated	Oxygen is not liberated.

Chemiosmotic Hypothesis

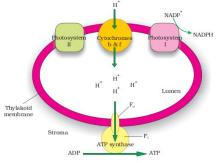

Figure 13.7 ATP synthesis through chemiosmosis

- It is the mechanism of ATP synthesis in thylakoid of chloroplast.
- When electrons are transported through the electron transport system (ETS)

- and protons accumulate inside the thylakoid membrane due to photolysis of water.
- Now electrons are passed through PS and protons are transported across the membrane.

Chemiosmosis requires;

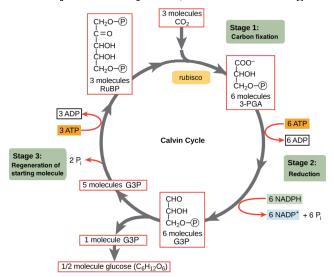

- A thylakoid membrane
- A protein pump
- A protein gradient
- ATP synthase enzyme.

Dark Reaction / Biosynthetic Phase:

- Next stage is the biosynthetic phase. In this, ATP and NADPH are used for synthesising the food / Glucose.
- This stage is also called the dark phase as it is independent of light.
- It takes place in the stroma of chloroplasts.
- In some plants, the first product of CO₂ fixation is a 3-carbon compound called 3-phosphoglyceric acid (PGA). These plants are said to adopt the C₃ pathway.
- In other plants, the first CO₂ fixation product is a 4-carbon compound called oxaloacetic acid. These plants are said to adopt the C₄ pathway.

Calvin Cycle (C₃ Cycle)

- The path of carbon in the dark reaction was traced by Melvin Calvin using radioactive carbon (14C).
- The primary acceptor of CO₂ was found to be a 5-carbon ketose sugar called Ribulose bisphosphate (RuBP). RuBP is used in a cyclic manner (regenerated) and a sugar is synthesised.
- 3 phases of Calvin cycle: Carboxylation, Reduction and Regeneration of RuBP

1. Carboxylation:

- o Ribulose 1, 5-bisphosphate combines with CO₂, and fixes it to a stable organic intermediate 3C compound called 3-phosphoglycerate (2 molecules). 3 PGA is the first stable product of this cycle.
- o Reaction catalysed by the enzyme RuBisCO (RuBP Carboxylase-Oxygenase)

2. Reduction

- o Here, two molecules each of ATP and NADPH are required for fixing one molecule of CO₂.
- o This stage contains a series of reactions.
- o Glucose is formed as a result of this series of reactions.

3. Regeneration

- o RuBP regenerates to enable the cycle to continue uninterrupted.
- o 1 ATP molecule is required.
- 4. For the formation of one molecule of glucose, six molecules of CO₂ need to be fixed; hence, six cycles are required.
- 5. ATP required:

For fixing 1 molecule of CO_2 – 3 (2 for reduction and 1 for regeneration) For fixing 6 molecules of CO_2 – 3 × 6 = 18 ATP

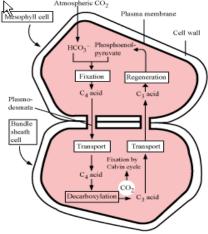

6. NADPH required:

For fixing 1 molecule of $CO_2 - 2$ (for reduction) For fixing 6 molecules of $CO_2 - 2 \times 6 = 12$ NADPH

7. Thus, the synthesis of 1 molecule of glucose requires 18 ATP and 12 NADPH.

C₄ Pathway (Hatch and Slack Pathway)

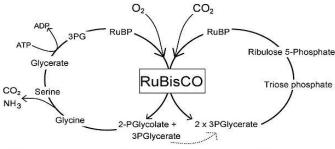

- Occurs in plants like maize, sugarcane plants adapted to dry tropical regions. The leaves of C₄ plants have *Kranz anatomy*. These plants show 2 types of
 - o photosynthetic cells , mesophyll cells and bundle sheath cells. Chloroplasts are dimorphic i.e., those is the mesophyll cells are granal and in bundle sheath Cells are agranal.

Hatch and Slack pathways

- C₄ plants can tolerate high temperature and high light intensity, show greater productivity of biomass, and lack photorespiration.
- Primary CO₂ acceptor: Phosphoenol pyruvate (PEP) a 3-carbon molecule.
- PEP Carboxylase fixes CO₂ in the mesophyll cells. It forms the 4-carbon compound oxaloacetic acid (OAA), and then other 4-carbon compounds malic acid
- These compounds are transported to the bundle sheath cells. There, C₄ acid breaks down to form C₃ acid and CO₂, and carbon dioxide enters the C₃ cycle).
- C₃ acid, so formed, is again transported to the mesophyll cells and regenerated back into PEP.
- C₃ cycle cannot directly occur in the mesophyll cells of C₄ plants because of the lack of the enzyme RuBisCO in these cells.
- RuBisCO is found in abundance in the bundle sheath cells of C₄ plants.

Photorespiration

Photorespiration Calvin Cycle

- It is a process in which there is no formation of ATP or NADPH, but there is utilization of ATP with release of CO₂. It is also considered a wasteful process.
- Photorespiration is responsible for the difference between C₃ and C₄ plants.
- At high temperature and high oxygen concentration, In C₃ plants, RuBP carboxylase function as oxygenase.
- RuBP oxidized into phosphoglycerate (3C) and phosphoglycolate (2C)
- 75% of carbon lost during oxygenation of RuBP
- There is loss of photosynthetically fixed carbon and no energy rich compounds are formed, so photorespiration is a wasteful process.

Differences between C₃ and C₄ Plants:

Characteristics	C3 Plants	C4 Plants	Choose from
Cell type in which the Calvin	Mesophyll	Bundle sheath	Mesophyll/Bundle sheath/both cycle takes
Cell type in which the initial			Mesophyll/Bundle sheath/both cycle takes
		Two: Bundle sheath and mesophyll	Two: Bundle sheath and mesophyll
How many cell types			One: Mesophyll
does the leaf have that fix CO2.	One: Mesophyll		Three: Bundle sheath, palisade.
			spongy mesophyll
which is the primary CO ₂ acceptor	RuBP	PEP	RuBP/PEP/PGA

Number of carbons in the primary	4	3	5/4/2003
which is the primary CO ₂ fixation product	PGA	OAA	PGA/OAA/RuBP/PEP
No. of carbons in the primary CO ₂ fixation	3	4	3/4/2005
Does the plant have RuBisCO?	YES	YES	Yes/No/Not always
Does the plant have PEP Case?	Not always	YES	Yes/No/Not always
Which cells in the plant have Rubisco?	Mesophyll	Bundle sheath	Mesophyll/Bundle sheath/none
CO2 fixation rate under high light conditions	Low	high	Low/ high / medium
whether photorespiration is	sometimes	negligible	High/negligible/sometim es
whether photorespiration is	sometimes	negligible	High/negligible/sometim es
whether photorespiration would	sometimes	negligible	High/negligible/sometim es
whether photorespiration would	sometimes	negligible	High/negligible/sometim es
Temperature optimum	20-25C	30-40 C	30-40 C/20-25C/above 40 C

Factors affecting rate of Photosynthesis:

Blackmans law of limiting factors.

When a physiological process is controlled by a number of factors, the rate of reaction depends on the lowest factor, so the factor which is the least/ limiting will determine the rate of Photosynthesis.

Photosynthesis is influenced by internal (plant) factors and external factors.

Light.

- Quality and intensity of light
- Wavelength of light between 400 nm 700 nm is called photosynthetically active radiation (PAR). High intensity of light destruct chlorophylls.

Temperature.

• High temperature denatures enzymes of biosynthetic phase and low temperature inactivates.

Carbon dioxide concentration.

In C3 plants upto 500 and in C4 plants upto 360

Availability of water.

Less water leads to - water stress, stoma closes, less carbon dioxide, reduce leaf expansion and less photosynthetic area.
